## Do Corporate Taxes Hinder Innovation?

*Abhiroop Mukherjee and Alminas Zaldokas*

### KEY POINTS

- ▶ Increases in corporate tax rates reduce innovation.
- ▶ However, corporate tax cuts do not seem to increase innovation significantly, at least in the short run.
- ▶ The effect of corporate taxes on innovation is consistent across R&D spending, patent filings and the introduction of new products by companies.
- ▶ Our findings show an asymmetry when it comes to policies affecting innovation – discouraging innovation is easy, encouraging innovation is more difficult and might take time.

### Issue

Both rising inequality and concerns over the competitiveness of national economies have emerged at the forefront of policy discourse today. As opportunities to transfer existing technologies from developed countries diminish, promoting innovation is of particular importance for emerging markets seeking to maintain growth momentum. Thus, policy-makers today are demanding policies that make firms in their countries more innovative, and hence competitive. At the same time, they also often argue in favor of higher taxes on corporations as a means to solve two other major problems in many societies today: rising inequality and bloated fiscal deficits.

But are these two objectives independent of one another, or are they in fact at loggerheads? Do higher corporate taxes also simultaneously reduce the innovativeness of firms, making them less competitive in a global marketplace?

Corporate taxes might have a direct effect on the innovation environment, and hence an economy's growth prospects. For one, the decline in after-tax profits from innovation projects following tax increases can cause innovators to redirect effort to other, non-innovative activities since the output from innovation is now likely to bring in lower after-tax earnings.

Tax changes may also discourage innovation if the change makes the tax schedule more progressive, which can happen for example, if the tax rate is increased on the highest income brackets leaving the lower brackets unchanged. This effect arises because innovation projects typically have higher upsides and are riskier than most other investment opportunities available to firms. For example, suppose a firm is choosing between two projects that cost the same. One is an innovation project that can lead to \$100 million in incremental sales with

## Assessment

Our research, recently published in the *Journal of Financial Economics*, examines the effects of corporate tax changes on patenting activity from two perspectives, providing insight into its consequence for future innovation activity. First, a country-level analysis of US patents shows how changes in the corporate tax rate affects firm patenting. Second, a comparative study of tax-changing states and similar, tax-steady states helps us account for general trends.

At the country level, countries which increased corporate taxes saw lower future innovation – their aggregate patent filing declined significantly in the three years after tax increases. Interestingly, countries which cut corporate tax rates did not benefit from any significant increases to future innovation.

This is consistent with the view that cutting funds for a prospective R&D idea quickly leads to reduced innovation. For instance, the firm might have to dismiss R&D personnel, reducing the chances of success for the project. Conversely, putting more money towards R&D does not lead to quick benefits. It takes time to hire and train additional R&D personnel, or to incentivize existing personnel to come up with new ideas. Because of this asymmetry, policies affecting innovation face a certain stickiness – discouraging innovation is easy, encouraging innovation takes time.

While our inter-country results show us the big-picture relationship between taxes and innovation, they do not distinguish between tax-effects on innovation and other,

**Figure 2: The effect of corporate tax changes on future innovation**

country-level economic conditions which may influence both tax policy and innovation.

To sharpen identification, we examine a within-country setting – specifically, the impact of corporate income tax changes at the state-level in the US. Unlike federal tax changes, which occur infrequently and affect all firms simultaneously, state tax changes happen more often and at different times. A state-level study helps us isolate the effects of tax changes from national changes in the economic and policy environments which may also affect firm innovation. This enables us to estimate the size of the tax

effect more precisely.

The main result of the analysis is that a one-standard-deviation change in corporate taxes (1.5%) induces 37% of firms to file one fewer patent within the next two years. This is a substantial effect given that the average firm files about 9.1 patents per year, reducing patenting relative to pre-tax change levels by roughly 5%.

Analysis shows that taxes also affect R&D investment, citations and the relevance of patents, as well as new product introductions by firms.

## Recommendations

Regarding fiscal policy, opponents of corporate taxation often suggest that corporate taxes discourage innovation, as they discourage risk-taking. The data agrees – firms respond to tax increases by filing less patents, investing less in R&D, and bringing fewer new products to market. Meanwhile, there is only weak evidence that cutting taxes incentivizes innovation activity. This asymmetry shows how discouraging innovation is straightforward, yet encouraging it is both difficult and takes longer. So while increasing corporate taxes may lead to short term fiscal gains, such gains may be offset by drops in innovation over a longer period. Given the importance of innovation in driving modern economic growth, governments

should think twice before making such a choice.

Our results speak to the ongoing debate on corporate tax reform in many countries. While governments and corporate leaders argue over the costs and benefits of such plans, our research strikes a cautionary note: cutting corporate taxes might not make firms in these countries more innovative, at least not in the short run.

And for countries thinking about easing fiscal deficits and inequality through tax hikes, our message is even clearer: tax increases will likely lead to lower innovation, and it will not be easy to reverse these losses quickly by cutting taxes back later.
